

# Calculating Stormwater Volume & TSS Reduction under Urban Tree Canopy in Wisconsin using Available Research

WAFSCM 2018 Annual Conference

November 8, 2018

Steve Gaffield & Dane Wudel

# Project Overview

- UW-Madison redevelopment stormwater study
- Lake flooding concern
- Ambitious stormwater volume control goal
  - Maintain native vegetation runoff
- TSS control driven by MS4 permit & TMDL

# Green Infrastructure Approach

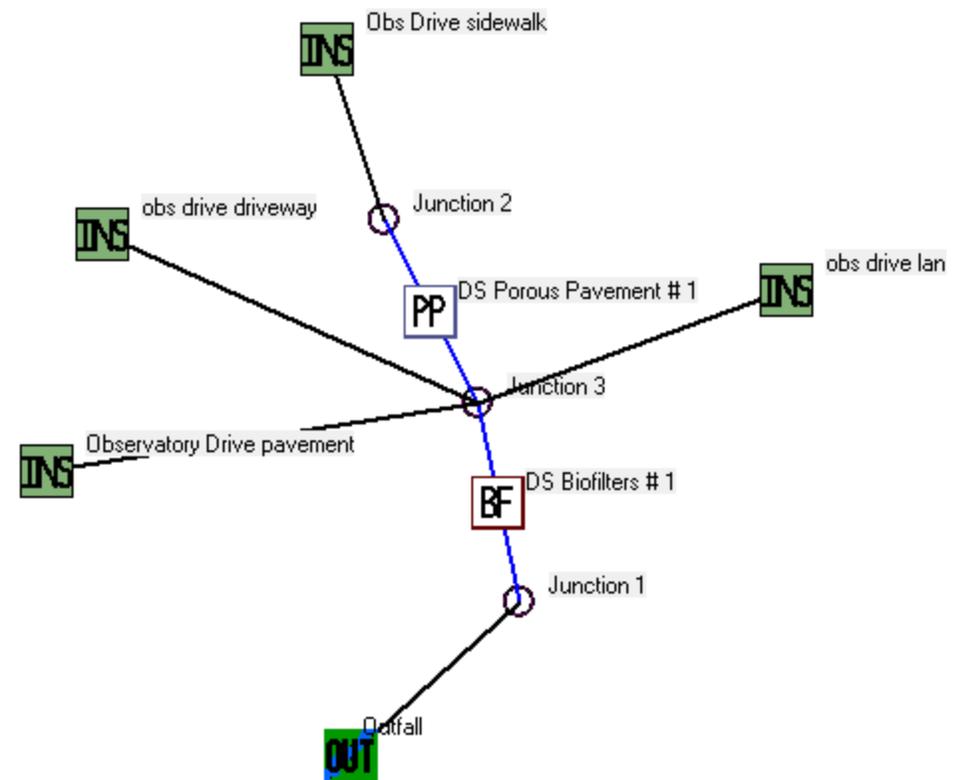

Chicago Center for Green Technology

- Bioretention
- Permeable pavement
- Green roofs
- Underground storage
- Rainfall harvesting & reuse
- Native landscaping
- Trees?

# WinSLAMM Model

- Requested by UW
- Compatible with other campus work
- Rainfall-runoff-pollutant loading model
- Widespread use & regulatory acceptance in Wisconsin
- Doesn't model trees

# Tree Canopy Interception

- Throughfall: hits ground below canopy
- Stemflow: flows down branches & trunks
- Interception: retained on leaves, branches & trunks
  
- Also: roots affect soil infiltration

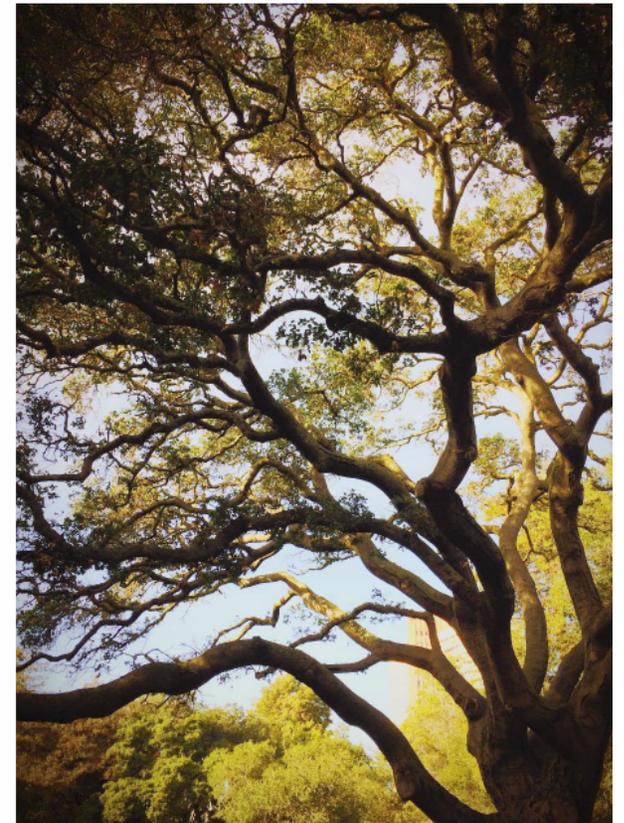

# National Interest in Urban Trees

- CWP & American Forests proposed stormwater credits
- USGS Wisconsin work on phosphorus export
- USGS & UW monitoring in Fond du Lac
- University research

Center for Watershed Protection

CREDITING FRAMEWORK PRODUCT #1:

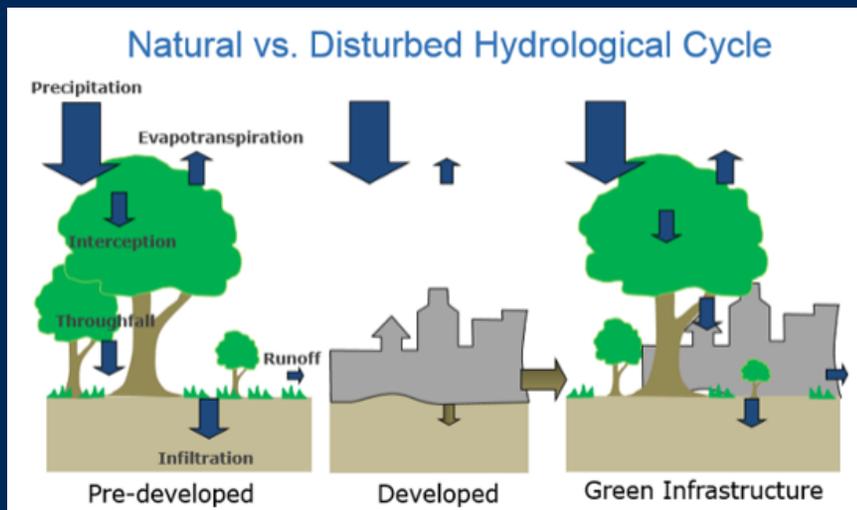

Literature Review

# Limited Modeling Tools

[www.itreetools.org/hydro](http://www.itreetools.org/hydro)

- US Forest Service (iTree)
  - Urban watershed scale
  - Predicts streamflow & water quality
- CWP credit calculator
  - Curve Number method
  - Annual runoff & loads
- Not site design tools

# Tree Modeling Approach

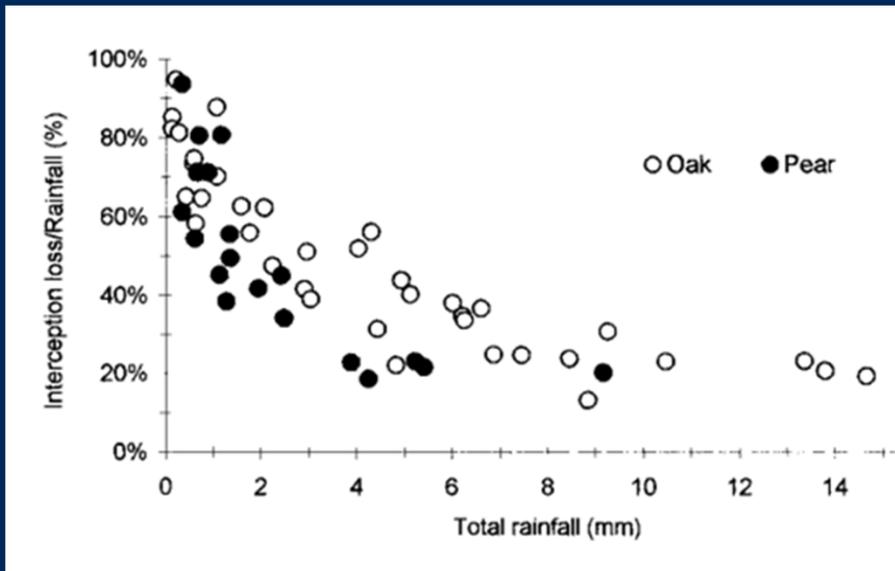

- Proof-of-concept
- Integrate with SLAMM
- Modify rainfall input to simulate canopy interception
- Change in soil & runoff generation not simulated

(USEPA, 2016)

# Tree Canopy Interception

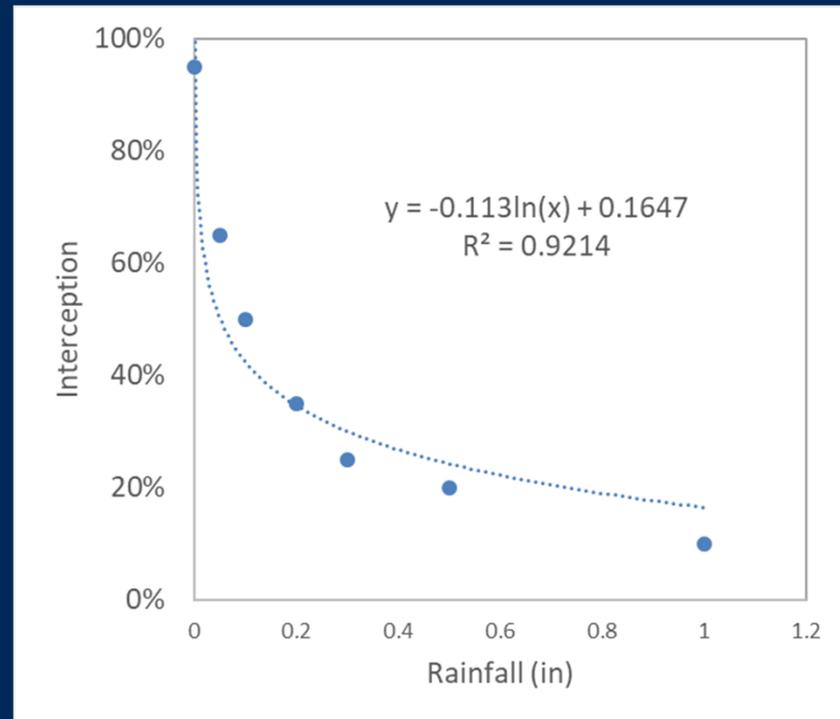

(Xiao et al., 2000)

- Monitoring data from California study
- No Wisconsin data
- Literature indicates interception increases with rainfall

# Modeling Interception

- Regression based on Xiao data
- Similar relationship in Belgian study (Staelens et al. 2007)
- Seasonal weighting for leaf growth

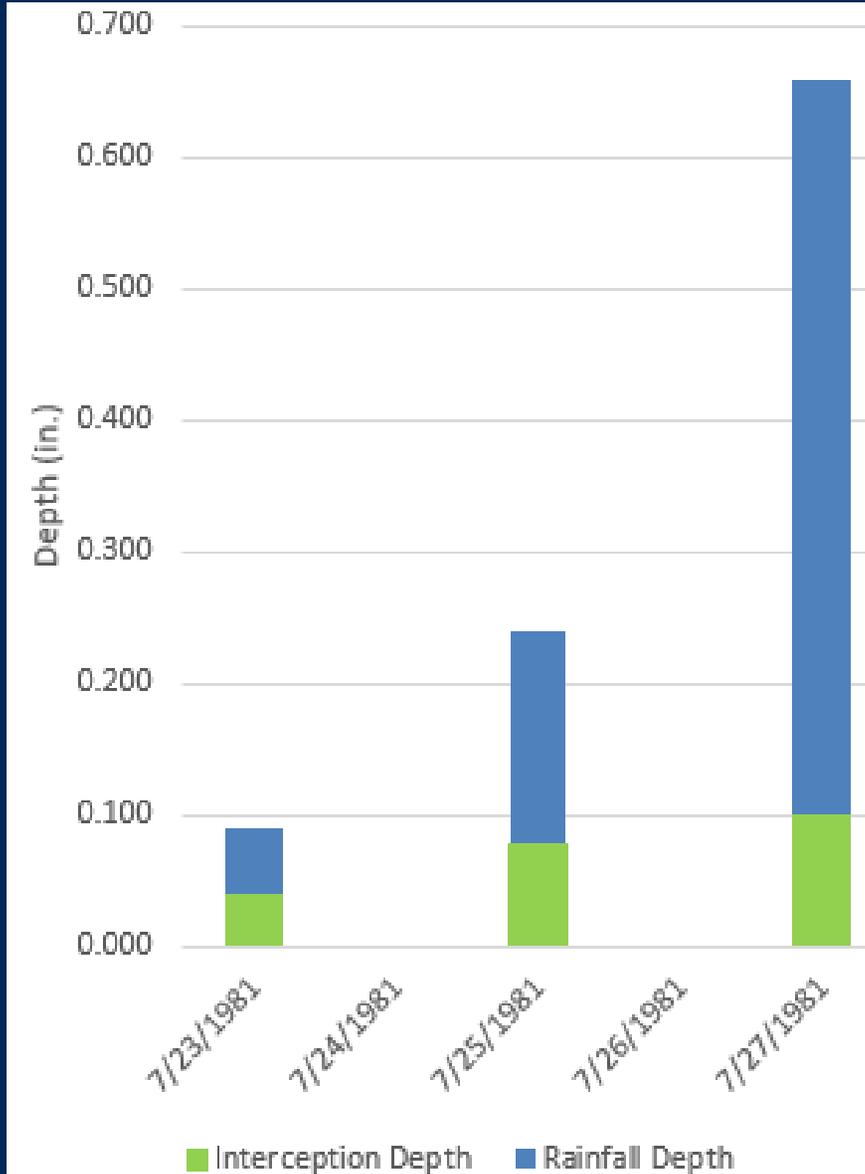

# Some Limitations

- Based on limited data (but could easily refine with more / local data)
- Only considers areas with full canopy coverage
- Does not consider antecedent moisture in the canopy

# Interception Simulation

- Applied regression to 1981 rainfall series
- Conservatively assumed 0.1" maximum interception depth
- Reduced rainfall accordingly
- Interception volume approx. 12% of annual rainfall

# Interception Simulation

April 12, 1981 example

Rainfall depth from 1981 series: 0.13"

% Interception =  $-0.113 \ln(0.13'') + 0.1647 = 39.5\%$

Leaf growth adjustment for April = 0.5

Interception depth =  $(0.13'')(39.5\%)(0.5) = 0.026''$

Adjusted precipitation =  $0.13'' - 0.026'' = 0.10''$

# Spreadsheet Model

Standard WinSLAMM rain file

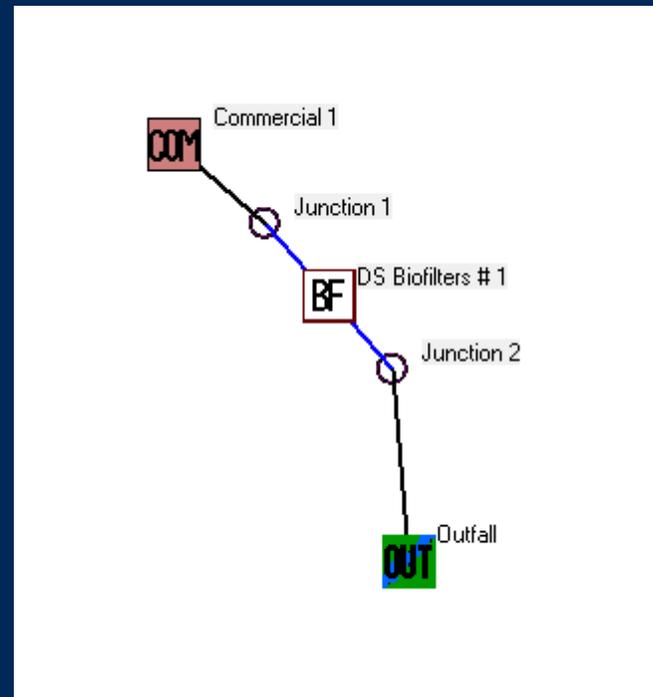

Modification for tree interception

| Rain Start |       | Rain Stop |       | Daily Depth (in) | Interception %         |                     | Interception (in)      |                     | Adjusted Daily Precip (in) |
|------------|-------|-----------|-------|------------------|------------------------|---------------------|------------------------|---------------------|----------------------------|
|            |       |           |       |                  | No seasonal adjustment | Seasonal Multiplier | No seasonal adjustment | Seasonal Multiplier |                            |

# Runoff Simulation

- Used edited rain file in WinSLAMM
- Source area annual runoff volume & TSS load reduced by 11% with tree cover
- Significantly improved “downstream” biofiltration performance

# Biofilter Performance Simulation

- Analysis to simulate retrofit
- Large contributing area relative to BMP size
- Evaluated runoff from 1 acre of parking lot under tree canopy (modified rainfall input)
- Varied the following:
  - Biofilter area
  - Depth of engineered soil
  - Native soil infiltration rate

# Biofilter Performance Results

- Volume and TSS reduction increased by 15-18% as compared to the same scenario without tree canopy cover

| BIOFILTER DETAILS       |                            |                                       | Runoff volume and TSS Reduction Resulting from Tree Canopy Cover |
|-------------------------|----------------------------|---------------------------------------|--|
| Area (ft <sup>2</sup> ) | Engineered Soil Depth (in) | Native Soil Infiltration Rate (in/hr) |  |
| 500                     | 24                         | 0.13                                  | 15.3%  |

# Lessons Learned

- Analyzing the effect of trees on urban stormwater management is a complex field
- Simple proof-of-concept analysis points to significant impacts provided by interception

# Next Steps?

## Research

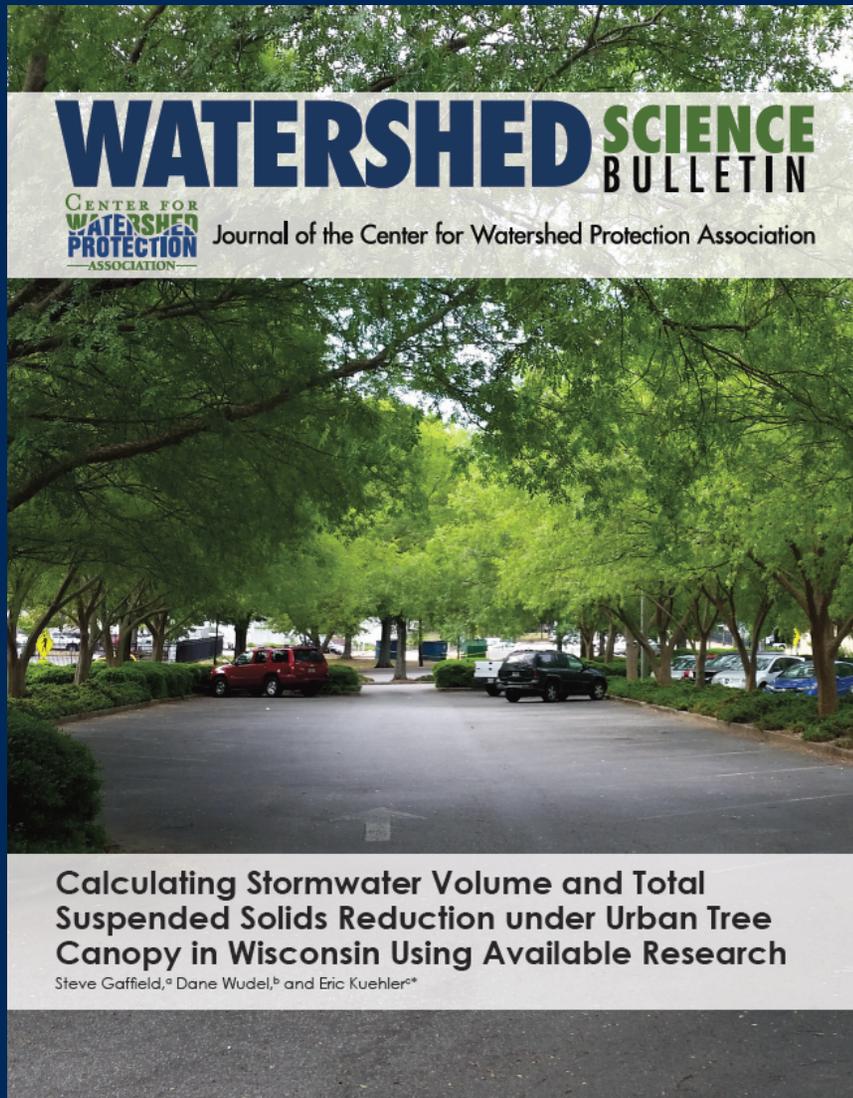

- More local data
  - Runoff volume
  - Runoff peak discharge
  - Water quality
- Model refinement
  - Partial canopy coverage
  - Different trees & ages
  - Infiltration effects
  - Nutrient loading

## Application

- Urban retrofits
- Apply interception calculation to other models
- Future policy development?
